

Text by Leonardo Betancur – Thermic Shield- i give a idea

The Thermic Shield

The thermic shield is thermic regulator and climatisator, this function is create another weather with steam of whater, ventilated in a low velocity to create temperature determinated with the steamed whater with a variation for each times of years.

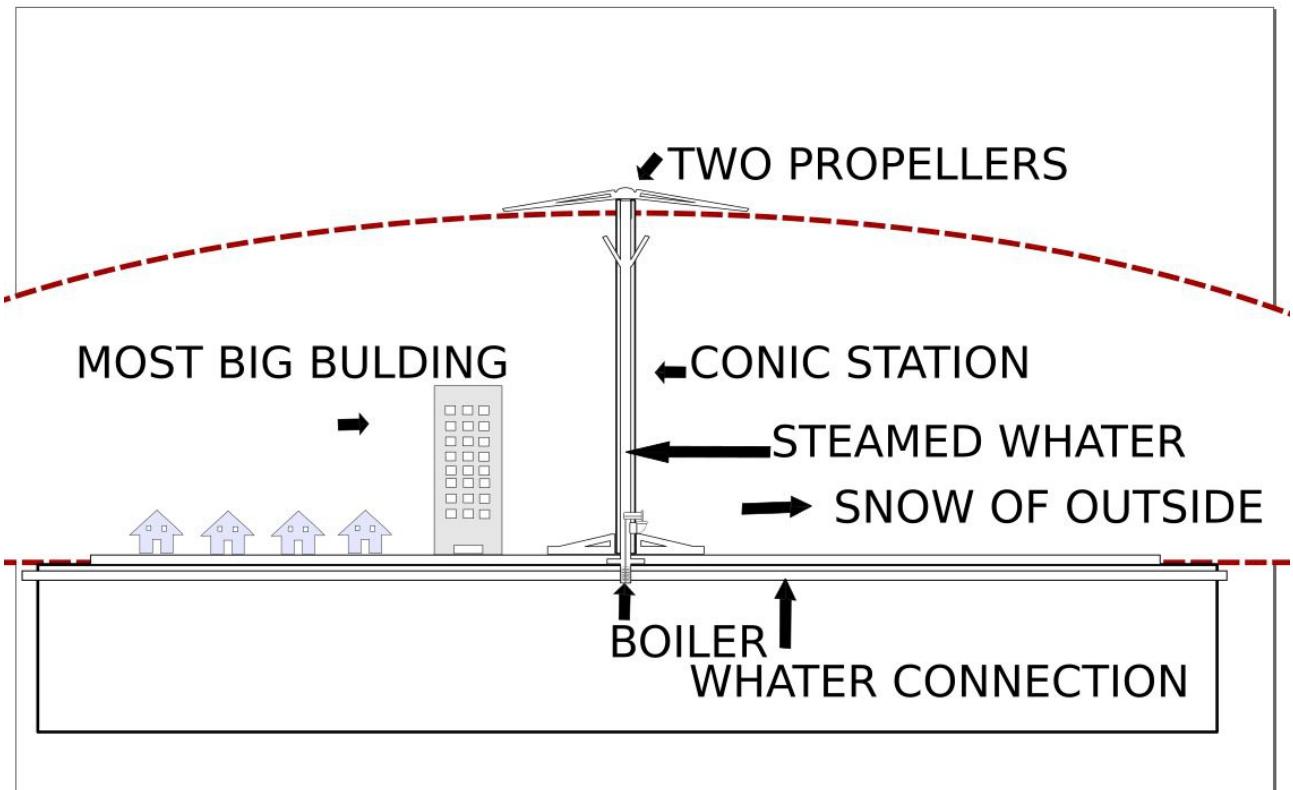

He turn with a propeller decalated impulsed with the steamed whater less than not dangereus km hours.

To keep the secuty about the velocity he have a limit of speed, because the proportional size and weight is not more big what the velocity of the polar wind and the distance of the ground is very long because propellers they are attached with a long conic station, in center of the station he pass the hot air in the conic body from the holes around the end of propellers to create a dispersion of the hot air and finally heat the air of the population.

The material can be created in inoxydable steel.

You can use the frozen snow to heat in the central boiler inside the station.

When you know the proportional size and weight to use agains the polar wind, the distance to ventilated, your choise depended of the area to heat.
